# HOW AGILENT CROSSLAB COMPLIANCE SERVICES INTEGRATE WITH QUALITY SYSTEMS AND REGULATIONS

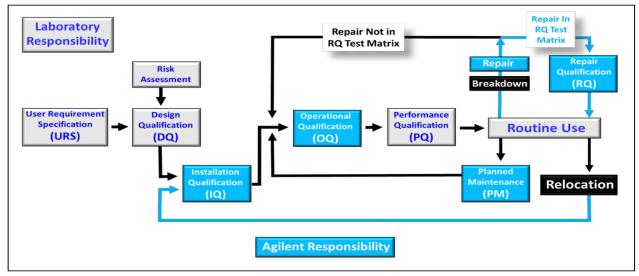

Agilent CrossLab Compliance Services

## Agilent CrossLab Compliance Services

Agilent CrossLab Compliance Services are designed to seamlessly integrate with traditional quality systems used by firms and recognized by regulatory agencies worldwide. Analytical instruments must be suitable for their intended use. This requirement is good science in all laboratories and a regulatory requirement in pharma and biopharma laboratories. A life-cycle process for documenting and testing the suitability of laboratory instruments should be followed and Agilent recommends the life cycle framework defined in USP General Chapter <1058> on Analytical Instrument Qualification (AIQ). USP <1058> defines the governing framework and requirements that need to be satisfied, but the laboratory is responsible for how they satisfy these requirements.

- The United States Pharmacopoeia (USP) is the only major pharmacopeia with a general chapter dedicated to analytical instrument qualification, making <1058> an important global regulatory reference. The information is provided in a scientific, risk-based approach to analytical instrument qualification (AIQ). However, the life-cycle framework contained within USP <1058> is not prescriptive in its implementation, making the embedded scientific and risk-based principles flexible and universally applicable.
- The scientific process followed by CrossLab uses the Agilent's Automated Compliance Engine (ACE) to deliver paperless electronic qualification. The life-cycle stages Agilent perform are highlighted in the life-cycle diagram below. As part of this life-cycle, Agilent can configure the qualification tests performed to align with user requirements.

USP <1058> AIQ Framework

**NOTE**: RQ services, described later in this document, can be added to standard qualification services.

# ACE Workflow and Equipment Qualification Plans (EQPs)

#### **Overview**

Within the ACE workflow, the qualification tests, setpoints, and limits are defined in an EQP that can be configured to ensure that testing satisfies user requirements. When the qualification work is complete, an Equipment Qualification Report (EQR) is issued. The electronic workflow used within ACE has significant data integrity advantages over traditional paper or Excel-based qualification protocols, as validated calculations can be performed directly using electronic data such as chromatograms and metrology test values. Several of the instrument life-cycle stages are the responsibility of the laboratory, Agilent can provide compliance consultancy services and documentation which can help customers satisfy these requirements. These additional services are not included in our typical qualification offering.

OE\*ā/^}dÜ^&[{{ ^}å^å Ô^ÈeŒÉIÈ~ĭ]

High-level ACE Qualification Workflow

#### Standard and User-defined Limits

(Hardware qualifications only)

EQPs are available for download and approval as standard documents with Agilent recommended tests, setpoints, and limits, or they can be electronically configured by approved personnel to align with user requirements and intended range of use requirements. The degree of configuration depends on the analytical technology, but most EQPs can be configured to some degree, and one feature that can typically be changed is test limits.

EQPs are designed to be configurable (dependent on the analytical technology and standard requirements), but including additional tests or setpoints can impact the qualification time and associated cost. If a test limit is changed, ACE includes the capability to report results against the Agilent approved limit and any customer required limits (that is, both can be reported simultaneously).

If a user-defined test limit is more stringent than an Agilent recommended limit, Agilent makes no guarantee or obligation regarding the instrument passing the tighter test specification requirements. It is important to appreciate that tests performed under conditions of use (that is, to satisfy pharmaceutical monograph and application requirements) can have different limits than those defined in the OQ. It is the continuum of the combined OQ, PQ, and any point of use testing performed each time the instrument is used that together satisfy regulatory requirements.

#### **User Requirements Specification (URS)**

The purpose of user requirements is to document the intended use of the instrument within the life-cycle process and quality management system ( $\Omega$ MS) being followed. Therefore, the URS is a customer / laboratory responsibility. Defining user requirements is often used to guide the customer in instrument selection and is stated as the first activity that should be followed in <1058>. The URS is important for two main reasons.

- It is a regulatory requirement for FDA and EU GMP that the intended use of the instrument and any software must be specified.
- Investment protection perspective means getting the right instrument for the right job.

Qualification protocols should test the instrument against any limits or specifications listed in the URS, which should document the intended range of use. Depending on the instrument complexity and how it is classified, a separate URS document may not be needed, but the URS requirements of the <1058> framework must be satisfied. A separate URS is almost always recommended for computerized systems.

An instrument performance specification is a product of the instrument development process by the supplier. It typically documents the performance the instrument can achieve. The URS should be based on intended use of the instrument and not the instrument specification. Additionally, if the intended use of a system changes, this may trigger a need to review the URS and associated qualification testing (for example, to ensure range of use is tested if used with a new analytical procedure).

Agilent offers compliance consultation services and documentation that can help customers address URS requirements.

## **Design Qualification (DQ)**

The main function of the DQ stage of the laboratory instrument life-cycle process is to document why the selected instrument is suitable. Typically, this includes consideration of the instrument specification, how the instrument will be qualified, and the QMS followed by the instrument manufacturer. All together, these confirm that instrument performance is capable of satisfying user requirements. Depending on laboratory instrument life-cycle policy or SOPs being followed, instrument requirements and the relationship between the URS and DQ stages may vary – but as long as the <1058> framework principles are satisfied, this is not a problem, as it is left to each laboratory to justify and document its specific approaches.

The responsibility for satisfying DQ requirements primarily lies with the laboratory, with support from the supplier.

Agilent's approach to satisfying DQ requirements of USP <1058> includes the following.

- All Agilent hardware and software laboratory products, including the ACE software used to deliver qualification services, are designed, manufactured, and tested according to Agilent internal quality life-cycle development procedures.
- Certificates of Agilent testing, validation, and conformance to standards are provided with new Agilent instruments and similar certification can be provided for ACE software.
- Agilent is capable of installation, support, preventive maintenance, on-going qualification, and re-qualification after repair and user training worldwide.

Agilent offers a compliance consultation service that can help customers with DQ documentation.

## **Installation Qualification (IQ)**

The main functions of the IQ stage are to document that laboratory is suitable (for example, critical systems typically include a site inspection / checklist), that the instrument is installed correctly in the environment, and IQ checks such as module start up are completed. IQ is provided and automated by ACE, which collects, checks, and tests Agilent hardware and software products for the following.

- 1. Purchase Order Details: Allows the customer to verify that the instrument being qualified matches their design requirements (if available) and purchase order.
- 2. Preparation and Installation Details: Gathers and records information about preparation and installation documents.
- 3. Documentation: Gathers and records information about reference and user manuals for initial installations.
- 4. Product Quality Assurance Details: Collects and records certificates and other forms that verify that the vendor has developed and built the product according to internal standards.
- 5. Startup: Verifies that all modules/components start up properly.
- 6. Installation Verification (software only): Verifies the correctness of all installation-related files.

#### **Operational Qualification (0Q)**

The main function of the OQ stage is to evaluate and document instrument performance at the intended operational range of use. OQ protocols should include a mix of metrology, functional, and operational tests. ACE qualification protocols include information about the test description and rational, setpoints, and the limits (acceptance criteria) for each technique, category, and instrument configuration.

00 is provided and automated by ACE. ACE checks and tests for Agilent hardware and software products include the following.

- Metrological tests such as flow, temperature, pressure, and so on that ensure that the system is performing within Agilent (or user) specifications.
- Qualification results are reported in the EQR, which can include details of all test certificates, standards, and training
  information for the engineer performing the work. (Note that the EQR can be configured to customer requirements.)
- System or "holistic" tests verify the combined functions of the various system components
- The qualification testing can be configured to ensure URS requirements, such as range of use are tested.

For software qualification, the OQ consists of automated diagnostics regression testing and verification of the software installation. This supports continued use of the software in regulated environments (at install and as part of supporting periodic review).

In line with regulatory requirements, the EQPs should be approved before work is performed and the EQR should be reviewed and approved when the work is complete (as illustrated in Figure 2). The EQR contains all the raw data, results, and relevant information and attachments for complete compliance and traceability.

#### **Mechanical Qualification (MQ)**

(Dissolution systems only)

The main function of the MQ stage is to document that the mechanical performance of the instrument meets specifications and is functioning properly.

#### **Performance Qualification (PQ)**

The main function of the PQ stage is to document that the instrument is fit for purpose under conditions of intended use and to create an approved framework that ensures the instrument continues to perform as required. Because instrument range of use is tested within the OQ stage, it is usually not necessary to test this during PQ. It should be noted that requirements for instrument maintenance and repair fall within the PQ life cycle stage within the USP <1058> framework, as they are components of ensuring the continued performance of the instrument.

The customer is responsible for satisfying PQ requirements. (NOTE: Agilent can provide a PQ for Dissolution systems only.)

It is important to note that PQ is a lifecycle activity and not a one-time event. PQ tests may include activities such as method validation or system suitability tests (SST), but in Agilent's opinion, SSTs contribute towards ensuring continued performance of the instrument (that is, PQ testing), but do may not fully satisfy <1058> PQ requirements.

#### **Repair Qualification (RQ)**

After an instrument is repaired, tests should be performed to evaluate the effectiveness of the repair and document that repaired instrument satisfies performance requirements. Agilent offers a service called Repair Qualification (RQ), which refers to the requalification of laboratory instrument hardware after a repair. For some laboratory systems, to document the performance after repair may require a full 0Q. However, for some modular or component-based systems, such as HPLC and GC for example, partial qualification testing can be justified. This is accomplished by performing the qualification tests that are applicable to only the module or system component related to the repair, reducing the time the instrument is out of service. Requalifying the instrument after repair is a regulatory requirement defined in USP <1058>.

Because of the modular/component-based dependency of RQ service, it is only available for the following instrument platforms: GC, GC/MS, LC, LC/MS, GPC, and SFC.

Agilent offers service contracts to repair and requalify an instrument during the period between scheduled annual OQs.

The level of retesting is prescribed in the RQ section of ACE: a form is displayed for the operator showing all types of repairs possible and the retesting required. Part of an example form for an LC system is shown below.

Re-Qualification After Repair		
Pump Strategies		
Repair/Replace Strategy	Modules	OQ Testing
Internal pump head parts, active inlet valve (or AIV cartridge), (parts of) check valves, reference valves, inlet manifold or pump drive, or taking pump head apart to clean (versus repair)	Any pump	Flow Accuracy & Precision
Pulse damper, pressure transducer	Any pump	Flow Accuracy & Precision
Multi-channel gradient valve	Quaternary	Flow Accuracy & Precision Gradient Composition

The full list of RQ repair and retest guidance is available for customer review.

#### **SERVICE DELIVERY METHODS**

# CUSTOMER APPROVAL OF ALTERNATIVE METHOD AND EQR STORAGE

**Agilent CrossLab Compliance Services** 

# Overview

Agilent recommends use of **Network ACE** for CrossLab qualification services that are enabled using the Agilent Automated Compliance Engine (ACE) software. Network ACE and Local ACE both access data directly (default methods) and are considered equivalent from a data integrity and data traceability perspective (see below). To provide additional flexibility in qualification service delivery, an alternative method is also available that accesses data indirectly. Use of the alternative method requires customer pre-approval using this form.

## Available Methods

Method	Definition
Network ACE (Agilent recommended)	ACE software is installed on a network node within the laboratory LAN infrastructure. Raw data locations are always captured in the equipment qualification report (EQR), which provides end to end traceability and a fully characterized data workflow in the delivery. This method requires collaboration with the customer to load ACE behind the customer firewall.
Local ACE	ACE software resides on an independent external drive that can be driven from the system controller, where the customer data system (CDS) resides. Because the external drive is connected to the CDS, the data integrity of this method is equivalent to that of the Network ACE delivery method. Raw data is imported directly into ACE by the Data Manager tool, with the data paths always captured in the report, which provides data traceability assurance.
Alternative (Requires pre-approval)	Pre-approval for this method is required to remove later questions on data integrity. ACE software is installed and run from a PC not directly connected to the CDS, such as the FSE laptop. System data files are transferred indirectly from the CDS to the laptop instead of directly like Network and Local ACE methods. <b>NOTE</b> : Software used in this method is qualified for data collection purposes; this method is <u>not</u> an option for software qualification.

# EQR Storage

Select the checkbox below to authorize Agilent to store a copies of the EQRs generated by ACE for Agilent internal assessments. The intention of the assessment is to evaluate the delivery of the qualification service, with a focus to improve delivery and assess the appropriateness of data integrity measures. The storage is exclusively for the internal assessment by Agilent and is not shared with other organizations. It is not to be considered a backup for the EQR provided at qualification delivery.

#### **Customer Approval of Alternative Method and EQR Storage**

Authorize Agilent to use the alternative method (check for approval):

Authorize Agilent to store EQRs for their internal assessment (check for approval):

# AGILENT CROSSLAB QUALIFICATION SERVICES

# **USE CASES FOR SERVICE DELIVERY**

Agilent CrossLab Compliance Services

#### Introduction

With heightened scrutiny of data integrity, the Agilent Automated Compliance Engine (ACE) software must be able to access instrument-generated raw data files one of two ways: directly, using the connection between network nodes or with the server; and indirectly, through storage in a secure transfer location. (In this document, data integrity refers to the who, what, and where of data used in generating an ACE equipment qualification report, or EQR.)

ACE includes three main service delivery methods that address data integrity requirements; the rest of this document provides details to determine which one best fits a customer's needs.

Regardless of the delivery method, ACE features and delivery procedures are compatible.

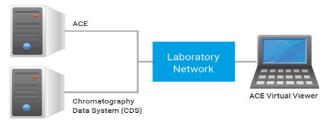

## **Network ACE (Agilent Recommended)**

#### Overview

ACE software is installed on a network node within the laboratory LAN infrastructure, which requires collaboration with the customer to load ACE behind their firewall. Raw data locations are always captured in the EQR, which provides end-to-end traceability and a fully characterized data workflow in the delivery.

#### Details

Typical Network ACE installation diagram

Installing ACE in a separate node (a.k.a. the host PC) on the same network as the system controller offers data traceability that is equivalent to an installation on the system controller itself. The system controller (where the CDS resides) and the ACE host PC are identified and seen by the server and subject to the customer's data access controls and general IT policies. The CDS's audit trail records data movements between nodes or between the client and server, and ACE's data traceability features identify the original data directory and therefore ensures end-to-end data traceability

The ACE host PC has a separate/partitioned drive for ACE

software. During ACE's installation, two services are setup on the operating system (OS): one for security and the other as a watchdog. Because the ACE host PC sits on the network as a shared drive, engineers access ACE through the networked drive: ACE is not installed on ACE Virtual Viewer PCs.

#### Requirements

Installation

- Install on a host PC with a separate drive (different from that of the OS)
- Attach to a network that clients can access
- 500 GB
- NTFS format
- User has local administration rights
- Customer installation instruction document is available

#### Operational

- User has an ACE node logon with a minimum of power user rights permissions; user also has a personal ACE account and password added through the ACE licensing tool
- Up to 5 users with 3 open sessions each can access the NDA simultaneously
- Exception to ports 11121-11141 on ACE node, clients, and switch's/Smart Hubs to be open on the network

#### Local ACE

#### **Overview**

ACE software resides on an independent drive that can be driven from the system controller, where the CDS resides. Because the drive is connected to the CDS, this method's data integrity is equivalent to preferred 1 method's. Raw data is imported directly into ACE by ACE's Data Manager tool, and data paths are captured in reports to provide data traceability.

ACE software resides on an independent drive that can be driven from the system controller, where the CDS resides. Because the drive is connected to the CDS, this method's data integrity is equivalent to the Network ACE method. Raw data is imported directly into ACE by ACE's Data Manager tool, and data paths are captured in reports to provide data traceability.

#### Details

ACE is designed to run from a dedicated drive, without leaving a footprint on the host PC. Therefore, it can be connected directly to the system controller (where the CDS resides) without altering the system's qualification status. For additional protection, the drive can be driven by another host PC on the same network; also, the drive can remain on site with the customer for use by the Agilent Field Service Engineer (FSE) during service deliveries only.

## **Alternative Method**

The ACE software is installed on and run from a PC not directly connected to the CDS, such as the FSE's laptop. System data files are transferred indirectly from the CDS to the laptop instead of directly like Network and Local ACE methods. This method requires customer pre-approval to remove later questions on data integrity.

## Standard 00 Test Suite

Fixed setpoints/limits

Key:

This document describes the test program for qualifying Agilent G1600 and G7100 CE systems. The following table lists all available tests.

Variances allowed

Test	Setpoints and Parameters	Limits
CDS Logon Verification	N/A	Evidence of logon used to collect qualification data
Noise and Drift	Wavelength: 254 nm	Noise < 0.05 mAU Drift < 2.00 mAU/hour
Cassette Temperature Stability	Temperature: 20.0°C	Stability < 1.0°C
		Average: $\geq$ -0.20°C and $\leq$ 0.20°C from setpoint
Holmium Test	Wavelength: 361.0 nm (G1600)	Accuracy < 2 nm
	Wavelength 1: 361.0 nm (G7100) Wavelength 2: 418.9 nm (G7100) Wavelength 3: 453.7 nm (G7100) Wavelength 4: 536.7 nm (G7100)	Accuracy < 2 nm
Scouting Run	Injection volume on column: 250 mbar*sec (50 $-$ 500)	N/A
Injection Precision	Injection pressure: 250 mbar*sec	Corrected area < 3.00 % Migration time < 2.00 %
Wavelength Accuracy	Wavelength 1: 236 nm (max) Wavelength 2: 258 nm (min) Wavelength 3: 325 nm (max)	Accuracy ≤ 3 nm (G1600) Accuracy ≤ 2 nm (G7100)
Response Linearity	Injection pressure: 250 mbar*sec	Correlation (r) > 0.9900
Injection Linearity	Injection pressure 1: 75 mbar*sec Injection pressure 2: 150 mbar*sec Injection pressure 3: 250 mbar*sec Injection pressure 4: 500 mbar*sec	Correlation (r) > 0.9900
High Voltage Stability	Voltage 1: 25.00 kV Voltage 2: –25.00 kV	Stability < 0.25 kV Average: $\geq$ -0.25 kV and $\leq$ 0.25 kV from setpoint
Replenishment	N/A	Qualitative (completes)

## **Test Design and Rationale**

#### **Overview**

Many GMP/GLP enforcement agency inspectors now ask firms to provide a risk assessment of their equipment and computer systems plus a science-based rationale for subsequent validation and qualification testing.

GENERAL RISK STATEMENT: Any laboratory chemical system used for raw material testing or final drug product / medical device testing in GMP or used in formal GLP studies will likely fall into a HIGH RISK category. This risk assessment will imply the need for IQ & OQ & on-going qualification. ANY USER SPECIFIC RISK ANALYSIS SUPERCEDES THIS GENERAL RISK STATEMENT. The rest of this section outlines the science-based rationale for each test in the Agilent hardware OQ plus a brief test design and procedure description.

The recommended set of hardware OQ tests described in this EQP derives from Agilent's interpretation of FDA, USP, and GAMP guidelines and other authoritative expert literature.

00 test design incorporates both modular and holistic testing, which is a proven and regulatory acceptable approach. When applicable, direct metrology is used to test pump flow rates and thermal-controlled column compartments, for example. Holistic chemical testing is used to evaluate critical instrument characteristics

When applicable, certified reference standards and calibrated equipment are used.

Considering the number of setpoints, parameters, and conditions of each recommended OQ test, the proven concepts of worst case, range, and representative have been applied. If a property or characteristic is known to have its worst performance at one end of a range of use, this is the setpoint that should be tested and other setpoints are not required. If a property or characteristic has no known worst case, testing at the high and low points of the range of use is required. If there are too many possible use cases and conditions to realistically test (and none is a worst case), a representative sample for test is the best approach.

#### **CDS Logon Verification**

Description: For traceability, evidence of the logon used to collect qualification data must be provided.

Procedure: Service delivery engineer captures evidence that is automatically included with this test in the EQR.

#### **Noise and Drift**

Description: This test gives an indication of detector sensitivity and stability.

Procedure: The signal is monitored at a specific wavelength over a 10-minute period. Noise is calculated as the average peakto-peak noise in a number of signal segments (ASTM noise). Drift is calculated as the slope of the linear regression of the signal. A G1600 instrument uses a red alignment interface without a capillary installed; the G7100 uses the green alignment interface with a capillary installed.

#### **Cassette Temperature Stability**

Description: Capillary Temperature can affect resolution, migration time stability, and even the volume injected. Therefore, the stability of the temperature during analysis is extremely important. Because temperature cannot be controlled directly inside the very small dimensions of the capillary, the temperature surrounding the capillary must be stable. The temperature gradient through the capillary walls must clearly be constant— as it's generated by Joule heating.

Procedure: The Agilent CE instrument uses a fast air flow thermostat based on a Peltier device with three independent measuring circuits that control Peltier function. The air temperature in the capillary closed loop is measured and controlled by the other two measuring units. Therefore, temperature stability (instead of single data points) is measured.

The temperature signal is collected during the noise and drift run. Stability is expressed as the delta between the highest and lowest temperature reading. The average cassette temperature is also evaluated to make sure the cassette temperature is stable within the setpoint range and regulated properly.

#### **Holmium Test**

Description: The wavelength of the detector needs to be accurate to achieve proper results.

Procedure: This procedure uses the internal holmium oxide filter to verify the wavelength calibration. The difference between expected and found values is given for each setpoint.

#### **Scouting Run**

Description: This test is used to determine the electropherogram for presence of expected peaks, sufficient run time, and proper integration events prior to the start of the actual qualification runs.

#### Injection Precision

Description: The test evaluates the corrected area and migration time of a traceable standard (4'-hydroxyacetophenone (pHAP). Migration time stability is an indirect control of the proper function of the temperature. Corrected area stability is a measure for a stable injection system and also a proper function of the temperature.

Procedure: A traceable standard is used to determine injection precision. Mean, standard deviation, and RSD of six standard deviations are calculated.

#### Wavelength Accuracy

Description: The wavelength of the detector needs to be accurate to achieve proper results.

Procedure: During the Injection Precision test, spectral data is collected. Some specific maximum and minimum wavelengths are compared against an expected result. Accuracy is expressed as the absolute difference between the measured and defined wavelength.

#### **Response Linearity**

Description: The detector response needs to be linear to assure reproducible results at different responses.

Procedure: This test uses traceable 4-hydroxyacetophenone solutions to check response linearity. Response Linearity is calculated by determining the correlation coefficient (r) of the corrected peak areas versus concentration. The origin is included as a data point in this calculation. Response Linearity is assessed over a wide enough range (0.1, 0.5, 1.0, and 5.0 mM) to ensure reproducibility at other concentrations

#### **Injection Linearity**

Description: The detector response needs to be linear to assure reproducible results at different injection volumes.

Procedure: This test uses a traceable 4-hydroxy acetophenone solution to check injection linearity. The sequence automatically runs methods that inject increasing amounts of sample from a single vial. Injection Linearity is calculated by determining the correlation coefficient (r) of the corrected peak areas versus concentration. The origin is included as a data point in this calculation. Injection Linearity is assessed over a wide enough range (75, 150, 2500, and 500 mbar\*s) to ensure reproducibility at other volumes.

#### **Voltage Stability**

Description: The applied voltage must be stable for reproducible migration times.

Procedure: During a 10-minute run, the voltage signal is collected. Stability is expressed as the delta between the highest and lowest voltage readings. The average high voltage is also evaluated to make sure the voltage is stable within setpoint range and regulated properly.

#### Replenishment

Description: If the replenishment is used, it needs to operate properly. If replenishment is not used, do not execute this test.

Procedure: This test verifies the vial handling and liquid flow in the replenishment system.

#### Allowed Variance Ranges

The simplest and most common occurrence is the Agilent Recommended test program - whereby the acceptance and approval refers to the fixed standards qualification tests and setpoints as recorded in the Agilent Recommended EQP. In this case, verbal confirmation of approval after customer review is sufficient for Agilent service to proceed with scheduling and delivery.

Agilent defines variances as changes to the default recommended values (as stated in the Agilent Recommended EQP) that fall within a range of well-defined allowable changes. These changes are considered to be within the intended use range of the system under test. The following table shows the allowed variance ranges for the test setpoints that can be configured. Agilent reserves the right to warrant conformance only when the tests definition lay within the maximum and minimum values shown.

#	Test		Agilent Setpoint			Units		Agilent point
			Min	Default	Max		Default	Max
1	Cassette Temperature Stability	G1600, G7100	4.0	20.0	60.0	°C	20.0	60.0
2	Injection Precision	G1600, G7100	50	250	500	mbar*s	250	500
3	Response Linearity	G1600, G7100	50	250	500	mbar*s	250	500
4	Injection Linearity	G1600, G7100	50	75	500	mbar*s	75	500
			50	150	500		150	500
			50	250	500		250	500
			50	500	500		500	500
